

Guide to Running VASP

What is VASP

The Vienna Ab initio Simulation Package (VASP) is a computer program for atomic scale materials modelling, e.g. electronic structure calculations and quantum-mechanical molecular dynamics, from first principles.

VASP computes an approximate solution to the many-body Schrödinger equation, either within density functional theory (DFT), solving the Kohn-Sham equations, or within the Hartree-Fock (HF) approximation, solving the Roothaan equations. Hybrid functionals that mix the Hartree-Fock approach with density functional theory are implemented as well. Furthermore, Green's functions methods (GW quasiparticles, and ACFDT-RPA) and many-body perturbation theory (2nd-order Møller-Plesset) are available in VASP.

In VASP, central quantities like the one-electron orbitals, the electronic charge density, and the local potential are expressed in plane wave basis sets. The interactions between the electrons and ions are described using norm-conserving or ultrasoft pseudopotentials, or the projector-augmented-wave method.

Please note that only the parallel version of VASP is installed on Supercomputing Wales, with the parallel executable named *vasp*. Supercomputing Wales can make this application available to selected users, as a VASP licence is required. Please contact the Supercomputing Wales helpdesk to request access.

Step 1 - Log in

The examples used in this guide are configured to run on the Cardiff Skylake *Hawk* cluster. Connect to *hawklogin.cf.ac.uk* with your Supercomputing user credentials using your preferred method (e.g. PuTTY from a Windows machine or ssh from any Linux terminal, thus ssh -1 your username hawklogin.cf.ac.uk

The steps below involve typing commands (in bold font) in the terminal window.

Step 2 - Load a VASP module

In common with most of the application guides in this series, we assume at the outset that the module of choice would be selected from those originally available on HPC Wales. Thus, a necessary first step would be to gain access to that module set by issuing the commands

module purge
module load hpcw

Note that the "module purge" command is required to prevent any unintentional collision with pre-existing modules. Subsequently issuing the module command

module avail

will provide visibility of and access to the entire set of HPCW modules.

A number of VASP packages are available.

List pre-installed VASP versions:

```
module avail vasp
To load the latest version:
module purge
module load hpcw
module load vasp/5.4.4
```

Note that successful execution of the associated executable relies on access to the MPI library specified by the module (intel-2017/4).

 Confirm the loaded modules. All dependencies are handled automatically via the module file:

```
module list
```

Step 3 - Create a directory

From your home directory, create a directory to hold the VASP data:

```
cd ~
mkdir VASP
```

Step 4 - Obtain a test case

Three benchmark test cases are provided with the installation at

```
/app/chemistry/vasp/5.4.1/sb-example
```

Copy the simplest of these contained in the tar file VaspHg.tar.gz to your user space:

```
cd ~/VASP
cp /app/chemistry/vasp/5.4.1/sb-example/VaspHg.tar.gz .
tar xvzf VaspHg.tar.gz
cd VaspHq
```

Note the full stop at the end of the cp line as this is important!

Step 5 - Submit a job

You are now ready to run this test case with the supplied SLURM job script.

The current directory should contain all required files to run a VASP job: INCAR is the central input file that determines 'what to do and how', POTCAR contains the pseudopotential for each atomic species used in the calculation, POSCAR contains the lattice geometry and the ionic positions, and optionally also starting velocities and predictor-corrector coordinates for a MD-run, KPOINTS contains the k-point coordinates and weights of the mesh-size for creating the k-point grid. The directory also contains a sample output file and a batch script.

- Submit the job using: sbatch VaspHg.Hawk.SLURM.q
- Check the job queue using: squeue
- When completed, the new output can be found in VASP.Hg.OUTCAR.Hawk.NCPUS=80.PPN=40.<Job ID>.

where < Job_ID> is the ID generated by the system.

• The output should be compared with the reference output file OUTCAR.ref to check that all is working correctly.

Step 6 - More test cases

More test cases are distributed with VASP. They can be found at

```
/app/chemistry/vasp/5.4.1/sb-example
```

a) Copy the second of these contained in the tar file VaspMoO3.tar.gz to your user space:

```
cd ~/VASP
cp /app/chemistry/vasp/5.4.1/sb-example/VaspMoO3.tar.gz .
tar xvzf VaspMoO3.tar.gz
```

Run this example using the script *vaspMoO3.SLURM.q*, and compare your job output with the reference output file

```
/app/chemistry/vasp/5.4.1/sb-example/VaspMoO3/VASP.MoO3.OUTCAR.Hawk.NCPUS=80.PPN=40.27794.
```

The job should take around 7 minutes using 80 cores if the case runs successfully.

b) Copy the third of these contained in the tar file VaspFeMoO4.tar.gz to your user space:

```
cd ~/VASP
cp /app/chemistry/vasp/5.4.1/sb-example/VaspFeMoO4.tar.gz .
tar xvzf VaspFeMoO4.tar.gz
```

Run this example using the script *vaspFeMoO4.SLURM.q*, and compare your job output with the reference output file

```
/app/chemistry/vasp/5.4.1/sb-example/
VaspFeMoO4/VASP.FeMoO4.OUTCAR.Hawk.NCPUS=160.PPN=40.14829.
```

The job should take around 60 minutes using 160 cores if the case runs successfully.

Step 7 - Scaling tests

Now you have checked the code is working look at the scaling of the code. To achieve this run the bulk MoO3 job above a number of times on differing core counts and calculate the speed up of the job relative to running on 80 cores. Remember if t(P) is the time on P cores the speed up S is given by S=t(80)/t(P). To do this

- Look at the batch script vaspMoO3.SLURM.q and you will see a line similar to #SBATCH --ntasks=80
- Using your favourite editor change the number at the end of this line to adjust the number of cores
- Re-run the job
- The elapsed time for the job can be found near the end of the OUTCAR file after the text string 'Elapsed time (sec)'.

Run the job on 40, 80, 120 and 160 cores and plot the speed up. What would you conclude about the scaling of the job?

Note: For larger number of cores it is important to find an appropriate value for the NPAR switch, which sets the parallelization over bands.
